Abstract
We consider the Membership and the Half-Space Reachability problems for matrices in dimensions two and three. Our first main result is that the Membership Problem is decidable for finitely generated sub-semigroups of the Heisenberg group over rational numbers. Furthermore, we prove two decidability results for the Half-Space Reachability Problem. Namely, we show that this problem is decidable for sub-semigroups of $GL(2, \mathbb{Z})$ and of the Heisenberg group over rational numbers.

1 Introduction

The algorithmic theory of matrix groups and semigroups is a staple of computational algebra [3] with numerous applications to automata theory and program analysis [7, 10, 12, 19, 20, 27] and has been influential in developing the notion of interactive proofs in complexity theory [1].

Two central decision problems on matrix semigroups are the Membership and Half-Space Reachability (see, e.g., [6]). For the Membership Problem the input is a finite set of generators $A_1, \ldots, A_k$ and a target matrix $A$, with all matrices being square and of the same dimension. The question is whether $A$ lies in the semigroup generated by $A_1, \ldots, A_k$. We emphasize that
we consider membership in finitely generated sub-semigroups, i.e., we seek to recover $A$ as a non-empty product of generators. In a related subgroup membership problem one additionally allows to take inverses of generators. The subgroup membership can clearly be reduced to the sub-semigroup membership and tends to be more tractable (e.g., the subgroup membership for polycyclic groups is well-known to be decidable [38], and the subgroup membership for the modular group $PSL(2, \mathbb{Z})$ is in PTIME [15]). For the Half-Space Reachability Problem the target matrix is replaced by vectors $u$, $v$ and a scalar $\lambda$, and the question is now whether there exists a matrix $A$ in the semigroup generated by $A_1, \ldots, A_k$ such that $u^\top A v \geq \lambda$. Geometrically the question is whether the orbit of $v$ under the action of the semigroup reaches a certain half-space with normal $u$. Closely related to these problems are the Vector Reachability and the Hyperplane Reachability$^1$ problems, which ask whether there exists a matrix $A$ in the semigroup generated by $A_1, \ldots, A_k$ such that $Au = u$ or such that $u^\top A v = \lambda$, respectively.

Undecidability of the Membership Problem has long been known (indeed, this was one of the earliest undecidability results—see A. Markov [28]). Subsequently a number of positive decidability results were obtained in the case of semigroups generated by commuting matrices over infinite fields [2, 20]. More recently, attention has focussed on integer matrices in dimension two. A classical result of [10] shows decidability of the Membership Problem for sub-semigroups of $GL(2, \mathbb{Z})$—the group of $2 \times 2$ integer matrices with integer inverses (equivalently, with determinants equal to $\pm 1$). Moreover, the semigroup membership for the identity matrix was shown to be NP-complete for $SL(2, \mathbb{Z})$ [4]. Furthermore, the Membership Problem is decidable for $2 \times 2$ integer matrices with nonzero determinant [32] and for $2 \times 2$ integer matrices with determinants equal to 0 and $\pm 1$ [33]. However it is still unknown whether the Membership Problem is decidable for all $2 \times 2$ integer matrices.

Going beyond dimension two, it has long been known that the Membership Problem is undecidable for general $3 \times 3$ integer matrices [31]. However the status of the Membership Problem for $GL(3, \mathbb{Z})$ is currently an outstanding open problem. Related to this, it was shown in [23] that for a two-element alphabet $\Sigma$, the monoid $\Sigma^* \times \Sigma^*$ cannot be embedded in $GL(3, \mathbb{Z})$. This fact suggests that undecidability proofs of the Membership Problem in other settings (such as [31]), which are based on encodings of the Post Correspondence Problem, are unlikely to carry over to $GL(3, \mathbb{Z})$. It is classical that the Membership Problem for $GL(4, \mathbb{Z})$ is undecidable [29, 5, 23]; thus it can reasonably be said that dimension three lies on the borderline between decidability and undecidability.

Our first main result (Theorem 7) concerns the Membership Problem for a simple subgroup of $GL(3, \mathbb{Z})$: the so-called Heisenberg group $H(3, \mathbb{Z})$, which comprises upper triangular integer matrices with ones along the diagonal. Since the Heisenberg group is polycyclic, the subgroup membership problem is decidable [38]. It was moreover recently shown in [23] how to decide membership of the identity matrix in finitely generated sub-semigroups of $H(3, \mathbb{Z})$. Our main theorem strengthens this last result to show decidability of the Membership Problem for $H(3, \mathbb{Z})$. In fact, like in [23], our argument works for Heisenberg groups of any dimension and even over the field of rational numbers, that is, for $H(n, \mathbb{Q})$.

Our proof relies on arguments developed in [23] but contains several significant new elements, including the use of linear programming, integer register automata, and matrix logarithms. The following algebraic property of $H(3, \mathbb{Z})$ is important for our construction: the subgroup generated by commutators of matrices from a given subset $G \subseteq H(3, \mathbb{Z})$ is isomorphic to a subgroup of $\mathbb{Z}$. Such property does not hold for the direct product of two

---

$^1$ In the literature the Hyperplane Reachability Problem is also called the Scalar Reachability Problem.
Heisenberg groups $H(3, \mathbb{Z})^2$ or for the group of $4 \times 4$ upper unitriangular matrices $\text{UT}(4, \mathbb{Z})$. This makes it challenging to generalize our argument to show decidability of the Membership Problem for $H(3, \mathbb{Z})^2$, $\text{UT}(4, \mathbb{Z})$ or other similar matrix groups.

In [24] a related problem was studied, called the Knapsack Problem. Namely, it was proved that the Knapsack Problem is decidable for $H(3, \mathbb{Z})$, that is, given matrices $A_1, \ldots, A_k$ and $A$ from $H(3, \mathbb{Z})$ one can decide whether there are non-negative integers $n_1, \ldots, n_k$ such that $A_1^{n_1} \cdots A_k^{n_k} = A$. Decidability of the Knapsack Problem is shown by reduction to the problem of solving a single quadratic equation in integer numbers (proved to be decidable in [13, 14]). By contrast, our decision procedure for the Membership Problem relies only on linear programming and integer linear arithmetic. As far as we can tell, there is no straightforward reduction in either direction between the Membership and Knapsack Problems for $H(3, \mathbb{Z})$.

The Vector Reachability, Hyperlane Reachability, and Half-Space Reachability Problems are all known to be undecidable in general (see [9, 16, 17]). The Vector and Hyperplane Reachability problems are known to be decidable for $\text{GL}(2, \mathbb{Z})$, as shown in [34]. For matrix semigroups with a single generator, the Half-Space Reachability Problem is equivalent to the Positivity Problem for linear recurrence sequences: a longstanding and apparently difficult open problem [30, 36]. Our second main result is that the Half-Space Reachability Problem is decidable for both $\text{GL}(2, \mathbb{Z})$ (Theorem 17) and $H(n, \mathbb{Q})$ (Theorem 20). For $\text{GL}(2, \mathbb{Z})$ we build on automata-theoretic techniques developed in [10], with the key insight being that the set of matrices in $\text{GL}(2, \mathbb{Z})$ with a positive value in a given entry can be represented as a regular language over the generators of $\text{GL}(2, \mathbb{Z})$. For $H(n, \mathbb{Q})$ we rely on a nontrivial result about the nonnegativity of quadratic forms over the integers from [13, 14] (related to the result used in [24] to solve the Knapsack Problem).

2 Preliminaries

The Heisenberg Group.

We use notations $I_n$ and $0_n$ for the identity matrix and for the zero matrix of size $n \times n$, respectively. For $n \geq 3$, the Heisenberg group of dimension $n$ is the group $H(n, \mathbb{R})$ of $n \times n$ real matrices of the form

$$A = \begin{pmatrix} 1 & a^\top & c \\ 0 & I_{n-2} & b \\ 0 & 0 & 1 \end{pmatrix},$$

where $a, b \in \mathbb{R}^{n-2}, c \in \mathbb{R}$. For brevity, we will often denote a matrix $A$ as in (1) by the triple $(a, b, c) \in \mathbb{R}^{n-2} \times \mathbb{R}^{n-2} \times \mathbb{R}$. It is easy to check that the product operation is given by

$$(a, b, c) \cdot (a', b', c') = (a + a', b + b', c + c' + a^\top b').$$

We use $\psi$ to denote the group homomorphism $\psi : H(n, \mathbb{R}) \to \mathbb{R}^{2n-4}$ given by $\psi(a, b, c) = (a, b)$.

The Heisenberg group $H(n, \mathbb{R})$ is a Lie group whose corresponding Lie algebra $\mathfrak{h}(n, \mathbb{R})$ comprises the vector space of $n \times n$ real matrices of the form

$$B = \begin{pmatrix} 0 & a^\top & c \\ 0 & 0_{n-2} & b \\ 0 & 0 & 0 \end{pmatrix},$$

where $a, b \in \mathbb{R}^{n-2}, c \in \mathbb{R}$.
where \(a, b \in \mathbb{R}^{n \times 2}\) and \(c \in \mathbb{R}\), together with the binary Lie bracket operation \([A, B] := AB - BA\) for \(A, B \in \mathfrak{h}(n, \mathbb{R})\). Note that \([A, B]\) has only zero entries except for the \((1, n)\)-entry. From this it is easy to check that \([\mathcal{C}, \mathcal{C}] = 0_n\) for all \(A, B, C \in \mathfrak{h}(n, \mathbb{R})\).

Given \(A \in \mathfrak{h}(n, \mathbb{R})\), as shown in (1), we define its logarithm \(\log(A) \in \mathfrak{h}(n, \mathbb{R})\) to be

\[
\log(A) := (A - I) - \frac{(A - I)^2}{2} = \begin{pmatrix}
0 & a^\top - \frac{1}{2}a^\top b \\
0 & 0-n-2 \\
0 & b \\
0 & 0 & 0
\end{pmatrix}
\]

Conversely, given \(B \in \mathfrak{h}(n, \mathbb{R})\), as shown in (2), we define its exponential \(\exp(B) \in \mathfrak{h}(n, \mathbb{R})\) to be \(\exp(B) := I + B + \frac{B^2}{2} = (a, b, c + \frac{1}{2}a^\top b)\). It is easy to verify that \(\log\) and \(\exp\) are mutually inverse and together induce a bijection between \(\mathfrak{h}(n, \mathbb{R})\) and \(\mathfrak{h}(n, \mathbb{R})\).

The following is a specialisation to \(\mathfrak{h}(n, \mathbb{R})\) of the Baker-Campbell-Hausdorff product formula (see [18, Chapter 5] for a details). Given a sequence of matrices \(B_1, \ldots, B_m \in \mathfrak{h}(n, \mathbb{R})\), we have

\[
\log(B_1 \cdots B_m) = \sum_{i=1}^{m} \log(B_i) + \frac{1}{2} \sum_{1 \leq i < j \leq m} [\log(B_i), \log(B_j)].
\]

Regular subsets of \(\text{GL}(2, \mathbb{Z})\).

We will use the notation \(\text{GL}(2, \mathbb{Z})\) for the general linear group of \(2 \times 2\) integer matrices, that is, \(\text{GL}(2, \mathbb{Z}) = \{M \in \mathbb{Z}^{2 \times 2} : \det(M) = \pm 1\}\). A matrix is called singular if its determinant is zero and nonsingular otherwise.

We will use the following encoding of the matrices from \(\text{GL}(2, \mathbb{Z})\) by words in alphabet \(\Sigma = \{X, N, S, R\}\). First, we define a mapping \(\varphi : \Sigma \rightarrow \text{GL}(2, \mathbb{Z})\) as follows:

\[
\varphi(X) = -I_2 = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \varphi(N) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \varphi(S) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad \varphi(R) = \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix}.
\]

We can extend \(\varphi\) to a morphism \(\varphi : \Sigma^* \rightarrow \text{GL}(2, \mathbb{Z})\) in a natural way. It is a well-known fact that morphism \(\varphi\) is surjective, that is, for every \(M \in \text{GL}(2, \mathbb{Z})\) there is a word \(w \in \Sigma^*\) such that \(\varphi(w) = M\). This presentation is not unique because of identities such as \(\varphi(SS) = \varphi(RRR) = \varphi(X)\). However, as explained below, every matrix \(M \in \text{GL}(2, \mathbb{Z})\) is represented by a unique word in the canonical form.

In the following definition, for \(n\) a positive integer and \(V \in \Sigma, V^n\) is the word consisting of \(n\) copies of \(V\), while \(V^0\) denotes the empty word.

**Definition 1.** A word \(w \in \Sigma^*\) is called canonical if it has the form

\[
w = N^\beta X^\gamma S^\delta R^{\alpha_1} S R^{\alpha_2} \cdots S R^{\alpha_n} S^\varepsilon,
\]

where \(\beta, \gamma, \delta, \varepsilon \in \{0, 1\}\) and \(\alpha_i \in \{1, 2\}\) for \(i = 1, \ldots, n\). In other words, \(w\) is canonical if it does not contain subwords \(SS\) or \(RRR\). Moreover, letter \(N\) may appear only once in the first position, and letter \(X\) may appear only once either in the first position or after \(N\).

The next proposition is a well-known fact.

**Proposition 2** ([25, 26, 32, 35]). For every matrix \(M \in \text{GL}(2, \mathbb{Z})\), there is a unique canonical word \(w\) such that \(M = \varphi(w)\).

**Definition 3.** A subset \(S \subseteq \text{GL}(2, \mathbb{Z})\) is called regular if there is a regular language \(L \subseteq \Sigma^*\) such that \(S = \varphi(L)\).
Definition 4. Two words $w_1$ and $w_2$ from $\Sigma^*$ are equivalent, denoted $w_1 \sim w_2$, if $\varphi(w_1) = \varphi(w_2)$. Two languages $L_1$ and $L_2$ in the alphabet $\Sigma$ are equivalent, denoted $L_1 \sim L_2$, if

(i) for each $w_1 \in L_1$, there exists $w_2 \in L_2$ such that $w_1 \sim w_2$, and
(ii) for each $w_2 \in L_2$, there exists $w_1 \in L_1$ such that $w_2 \sim w_1$.

In other words, $L_1 \sim L_2$ if and only if $\varphi(L_1) = \varphi(L_2)$. Two finite automata $A_1$ and $A_2$ with alphabet $\Sigma$ are equivalent, denoted $A_1 \sim A_2$, if $L(A_1) \sim L(A_2)$.

The following theorem is a crucial ingredient of our decidability results.

Theorem 5 ([32]). For any automaton $A$ over the alphabet $\Sigma = \{X, N, S, R\}$, there exists an automaton $\text{Can}(A)$ such that $\text{Can}(A)$ is equivalent to $A$ and $\text{Can}(A)$ accepts only canonical words. Furthermore, $\text{Can}(A)$ can be constructed from $A$ in polynomial time.

Corollary 6. Regular subsets of $\text{GL}(2, \mathbb{Z})$ are effectively closed under Boolean operations. Namely, given two regular languages $L, L' \subseteq \Sigma^*$, we can algorithmically construct in polynomial time regular languages $L^\cup, L^\cap$ and $L'$ such that $\varphi(L^\cup) = \varphi(L) \cup \varphi(L')$, $\varphi(L^\cap) = \varphi(L) \cap \varphi(L')$, and $\varphi(L') = \text{GL}(2, \mathbb{Z}) \setminus \varphi(L)$.

Decision problems for matrix semigroups.

If $\mathcal{G}$ is a finite collection of matrices, then $\langle \mathcal{G} \rangle$ denotes the semigroup generated by $\mathcal{G}$, that is, $A \in \langle \mathcal{G} \rangle$ if and only if there are matrices $A_1, \ldots, A_k \in \mathcal{G}$ such that $A = A_1 \cdots A_k$.

In this paper we will consider the following decision problems for matrix semigroups:

- **The Membership Problem:** Given a finite collection of matrices $\mathcal{G}$ and a “target” matrix $A$, decide whether $A$ belongs to $\langle \mathcal{G} \rangle$.

- **The Half-Space Reachability Problem:** Given a finite collection of matrices $\mathcal{G}$, two vectors $u, v$ and a scalar $\lambda$, decide whether there exists a matrix $A \in \langle \mathcal{G} \rangle$ such that $u^T A v \geq \lambda$. In other words, decide whether it is possible to reach the half-space $\mathcal{H} = \{x : u^T x \geq \lambda\}$ using matrices from $\mathcal{G}$ starting from an initial vector $v$.

When we talk about the *Membership Problem for GL(2, Z)* or for the Heisenberg group $H(n, \mathbb{Q})$, we mean that $A$ and the matrices from $\mathcal{G}$ belong to $\text{GL}(2, \mathbb{Z})$ or $H(n, \mathbb{Q})$, respectively. Similarly, in the *Half-Space Reachability Problem for GL(2, Z)* or $H(n, \mathbb{Q})$ we assume that $\mathcal{G}$ is a finite subset of $\text{GL}(2, \mathbb{Z})$ or $H(n, \mathbb{Q})$, respectively, and furthermore we assume that the vectors $u, v$ have rational coefficients and $\lambda$ is a rational number.

3 The Membership Problem for the Heisenberg Group

Let $H(n, \mathbb{Z})$ and $H(n, \mathbb{Q})$ be subgroups of $H(n, \mathbb{R})$ comprising all matrices with integer and rational entries, respectively. In this section we will prove our first main result.

Theorem 7. The Membership Problem for $H(n, \mathbb{Z})$ is decidable.

We first give an overview of our decision procedure. Let $\mathcal{G} = \{A_1, \ldots, A_k\}$ be a finite set of generators from $H(n, \mathbb{Z})$ and $A \in H(n, \mathbb{Z})$ be a target matrix. The idea is to partition the set of generators $\mathcal{G}$ into two sets $\mathcal{G}_+$ and $\mathcal{G}_0$. The definition of $\mathcal{G}_+$ is such that there is a computable upper bound on the number of occurrences of a matrix from $\mathcal{G}_+$ in any string of generators whose product equals the target matrix $A$. The definition of $\mathcal{G}_0$ is such
that the image of the semigroup generated by \(G_0\) under the homomorphism \(\psi\) is a subgroup of \(\mathbb{R}^{2n-4}\) (i.e., the image is closed under inverses). We then proceed by a case analysis according to whether or not \(G_0\) is a commutative set of matrices. If \(G_0\) is commutative then the Membership Problem can be reduced to solving a system of linear equations over non-negative integer variables. If \(G_0\) is not commutative then we reduce the Membership Problem to a reachability query in an integer register automaton.

**Partitioning the Set of Generators.**

In the rest of this section we work with an instance of the Membership Problem in which the generators are \(A_i = (a_i, b_i, c_i)\), for \(i = 1, \ldots, k\), and the target matrix is \(A = (a, b, c)\). Recalling the homomorphism \(\psi: \mathbb{H}(n, \mathbb{Z}) \to \mathbb{Z}^{2n-4}\), let us define \(v_i := \psi(A_i) = (a_i, b_i)\), for \(i = 1, \ldots, k\), and \(v := \psi(A) = (a, b)\).

A set \(C \subseteq \mathbb{R}^n\) is called a cone if \(\sum_{i=1}^k r_i u_i \in C\) for all \(r_1, \ldots, r_k \in \mathbb{R}_{\geq 0}\) and \(u_1, \ldots, u_k \in C\). The dual of a cone \(C \subseteq \mathbb{R}^n\) is the cone defined as

\[
C^* := \{ x \in \mathbb{R}^n : x^\top y \geq 0 \text{ for all } y \in C \}.
\]

We will use the fact that \(C = C^{**}\), i.e., a cone is equal to its double dual [8, Chapter 2.6.1].

We write \(\text{Cone}(v_1, \ldots, v_k)\) for the cone generated by the vectors \(v_1, \ldots, v_k\). We now partition the set of generators \(G\) into two disjoint sets \(G_0, G_+\), where

\[
G_0 := \{ A_i : \forall u \in \text{Cone}(v_1, \ldots, v_k)^* \quad v_i^\top u = 0 \} \quad \text{and} \quad G_+ := \{ A_i : \exists u \in \text{Cone}(v_1, \ldots, v_k)^* \quad v_i^\top u > 0 \}.
\]

We can determine the sets \(G_0\) and \(G_+\) using linear programming [37]. Without loss of generality we can assume that \(G_0 = \{A_1, \ldots, A_\ell\}\) for some \(\ell \geq 0\).

We show how to compute a bound \(\beta > 0\) such that for every sequence \(S = B_1, \ldots, B_m\) of elements of \(G\) whose product is equal to the target matrix \(A\), the number of indices \(i\) such that \(B_i \in G_+\) is at most \(\beta\). By definition of \(G_+\), for each \(i \in \{1, \ldots, \ell\}\), there exists \(u_i \in \text{Cone}(v_1, \ldots, v_k)^*\) such that \(v_i^\top u_i > 0\). Since \(v_j^\top u_i \geq 0\) for all \(j \neq i\), \(S\) contains at most \(\sum_{i=1}^\ell \frac{v_i^\top u_i}{v_i^\top u_i}\) occurrences of matrix \(A_i\) (or no occurrences if \(v_i^\top u_i \leq 0\)). Thus we may define

\[
\beta := \sum_{i=1}^\ell \frac{v_i^\top u_i}{v_i^\top u_i}
\]

where the sum is take over the indices \(i = 1, \ldots, \ell\) such that \(v_i^\top u_i > 0\).

We now consider two cases according to whether \(G_0\) is a commutative set of matrices.

**Case I: \(G_0\) is commutative.**

Consider a sequence \(S = B_1, \ldots, B_m\) of elements of \(G\). Let \(B_{i_0}, \ldots, B_{i_\ell}\) be the subsequence of \(S\) containing all occurrences of elements of \(G_+\) in \(S\), where \(0 = i_0 < i_1 < \ldots < i_s < i_{s+1} = m + 1\). For \(i \in \{1, \ldots, \ell\}\) and \(j \in \{1, \ldots, s + 1\}\), write \(n_{i,j}\) for the number of occurrences of \(A_i \in G_0\) in the subsequence of \(S\) lying strictly between \(B_{i_{j-1}}\) and \(B_{i_j}\) (where \(B_0\) is interpreted as the beginning of \(S\) and \(B_{m+1}\) as the end of \(S\)). The idea is to write a formula for \(\log(B_1 \cdots B_m)\) that is a linear form in the variables \(n_{i,j}\).

Indeed by Equation (3), writing \(C_{ij} := \log(B_{ij})\) for \(j = 1, \ldots, s\) and \(D_i := \log(A_i)\) for \(i = 1, \ldots, \ell\), we have

\[
\log(B_1 \cdots B_m) = \sum_{j=1}^s C_{ij} + \sum_{i=1}^\ell \sum_{j=1}^{s+1} n_{i,j} D_i + \sum_{1 \leq i < j' \leq s} [C_{ij}, C_{i'j'}] + \sum_{i=1}^\ell \sum_{1 \leq i < j' \leq s+1} n_{i,j'}[D_i, C_{i'j'}].
\]
An important observation is that the above formula has no quadratic terms due to commutativity of $G_0$. Now $B_1 \cdots B_m = A$ if and only if $\log(B_1 \cdots B_m) = \log(A)$. Setting the right-hand-side of (4) equal to $\log(A)$ yields a linear Diophantine equation in variables $n_{i,j}$.

The form of this equation is determined by the subsequence of matrices $B_1, \ldots, B_m$ lying in $G_+$. Recall that we can without loss of generality restrict attention to the case that $s \leq \beta$ and thus we reduce the question of whether $A$ lies in the semigroup generated by $G$ to the solubility of finitely many linear equations in nonnegative integers.

**Case II: $G_0$ is not commutative**

Let $G_0 = \{A_1, \ldots, A_r\}$ for some $\ell \geq 2$ such that $A_1$ and $A_2$ do not commute. Recall that by definition of $G_0$ it holds that $v_1^i u = 0$ for all $u \in \text{Cone}(v_1, \ldots, v_k)^*$ and $i = 1, \ldots, \ell$. Therefore,

$$\text{Span}(v_1, \ldots, v_\ell) \subseteq \text{Cone}(v_1, \ldots, v_k)^* = \text{Cone}(v_1, \ldots, v_k).$$

(5)

Following ideas from [23], we will show that there exist integers $p > 0$ and $q < 0$ such that $M_+ = (0, 0, p)$ and $M_- = (0, 0, q)$ and both lie in the semigroup generated by $G$.

Indeed, from Equation (5) it follows that $-(v_1 + v_2)$ lies in $\text{Cone}(v_1, \ldots, v_k)$. Thus there exist $r_1, \ldots, r_k \in \mathbb{R}_{\geq 0}$ with $r_1, r_2$ strictly positive such that $\sum_{i=1}^k r_i v_i = 0$. But since the vectors $v_i$ have integer coefficients we can solve the above equation in natural numbers $r_1, \ldots, r_k$ with $r_1, r_2 > 0$. Taking a sequence of matrices $B_1, \ldots, B_m$, drawn from $G$, such that $B_1 = A_1$, $B_2 = A_2$ and such that matrix $A_t$ appears $t$ times in the sequence for $i \in \{1, \ldots, k\}$, we obtain $\psi(B_1 \cdots B_m) = 0$. Since $\psi$ is a homomorphism to a commutative group we have that $\psi(B^t_{\sigma(1)} \cdots B^t_{\sigma(m)}) = 0$ for all $t \geq 1$ and permutations $\sigma \in S_m$.

Write $C_i = \log(B_i)$ for $i = 1, \ldots, m$. Applying the Baker-Campbell-Hausdorff Formula (3), we have that for any positive integer $t$ and permutation $\sigma \in S_m$,

$$\log(B^t_{\sigma(1)} \cdots B^t_{\sigma(m)}) = t \sum_{i=1}^m C_{\sigma(i)} + \frac{t^2}{2} \sum_{i < j} [C_{\sigma(i)}, C_{\sigma(j)}].$$

(6)

We show that we can obtain the desired matrices $M_+$ and $M_-$ as $M_+ := B^t_{\sigma(1)} \cdots B^t_{\sigma(m)}$ and $M_- := B^t_{\sigma(m)} \cdots B^t_{\sigma(1)}$ for some permutation $\sigma \in S_m$ and large enough $t$.

Let $\sigma_0 \in S_m$ be the permutation that transposes 1 and 2. Write also $id \in S_m$ for the identity permutation. Defining $\delta_\sigma := \sum_{i < j} [C_{\sigma(i)}, C_{\sigma(j)}]_{1,n}$, we have $\delta_{id} - \delta_{\sigma_0} = 2[C_1, C_2]_{1,n} \neq 0$ since $B_1, B_2$ do not commute. Hence there exists $\sigma \in \{id, \sigma_0\}$ with $\delta_\sigma \neq 0$. Defining the reverse permutation $\sigma' \in S_m$ by $\sigma'(i) = \sigma(m + 1 - i)$ for $i = 1, \ldots, m$, we moreover have $\delta_{\sigma'} = -\delta_\sigma$, and thus we may suppose that $\delta_\sigma > 0$ and $\delta_{\sigma'} < 0$. It remains to note, by inspection of (6), that for $t$ sufficiently large, if $\delta_\sigma \neq 0$ then the sign of the $(1,n)$-entry of $\log(B^t_{\sigma(1)} \cdots B^t_{\sigma(m)})$ is equal to the sign of $\delta_\sigma$. But since $\log(B^t_{\sigma(1)} \cdots B^t_{\sigma(m)})$ has zeros in all entries, except for the $(1,n)$-entry, this entry is in fact equal to the $(1,n)$-entry of $B^t_{\sigma(1)} \cdots B^t_{\sigma(m)}$.

So, under the assumption that $G_0$ is not commutative we have shown that one can compute integers $p > 0$ and $q < 0$ such that $M_+ = (0, 0, p)$ and $M_- = (0, 0, q)$ are in $G$. It follows that $(\text{Cone})$ contains the group $N' = \{(0,0,c) \in H(n,\mathbb{Z}) : c \equiv 0 \pmod{m}\}$, where $m = \text{gcd}(p, q)$. Since

$$(a,b,c) \cdots (0, 0, c') = (0, 0, c') \cdots (a,b,c) = (a,b,c + c'),$$

we have the following equivalence for the target matrix $A = (a,b,c)$:

$$A = (a,b,c) \in (\text{Cone}) \iff \exists B \in (\text{Cone}) \text{ such that } AB^{-1} \in N'$$

$$\iff \exists B \in (\text{Cone}) \text{ such that } B = (a,b,c') \text{ and } c' \equiv c \pmod{m}.$$
To decide whether \( \langle G \rangle \) contains a matrix \( B = (a, b, c') \) with \( c' \equiv c \pmod{m} \), we will use register automata. Let \( d = n - 2 \) and consider the following finite automaton with \( 2d \) registers:

\[
Q = (\{A_1, \ldots, A_k\}, S, R_1, \ldots, R_d, T_1, \ldots, T_d, S_0, \delta, F),
\]

where the alphabet of \( Q \) is equal to the set of generator matrices \( G = \{A_1, \ldots, A_k\} \), and the set of states \( S \) is equal to

\[
S = \{(s_1, \ldots, s_d, t_1, \ldots, t_d, u) : s_i, t_i, u \in \{0, \ldots, m - 1\} \text{ for } i = 1, \ldots, d\}.
\]

Intuitively, \((2d + 1)\)-tuples from \( S \) store the values of a vector \((a, b, c)\) modulo \( m \), and the registers \( R_1, \ldots, R_d \) and \( T_1, \ldots, T_d \) store the values of \( a \) and \( b \), respectively.

The initial state of \( Q \) is \( S_0 = (0, \ldots, 0) \), and the initial values of all the registers are zeros. The transition function \( \delta \) is defined as follows. Suppose \( Q \) is in a state \((s_1, \ldots, s_d, t_1, \ldots, t_d, u)\), and the current values of \( R_i \) and \( T_i \) are \( r_i \) and \( t_i \), respectively, for \( i = 1, \ldots, d \). If \( Q \) reads a letter \( A_i = (a_i^1, \ldots, a_i^k, b_i^1, \ldots, b_i^d, c') \), then it moves to the state \((s'_1, \ldots, s'_d, t'_1, \ldots, t'_d, u')\), where for each \( i = 1, \ldots, d \):

\[
s'_i \equiv s_i + a_i^f \pmod{m} \quad \text{and} \quad t'_i \equiv t_i + b_i^l \pmod{m},
\]

\[
u' \equiv u + c + s_1 b_1^f + \cdots + s_d b_d^f \pmod{m}.
\]

Also, the new value of \( R_i \) is \( r_i + a_i^l \) and the new value of \( T_i \) is \( t_i + b_i^l \).

The set \( F \) of final states consists of one state that corresponds to the values of the target matrix \( A = (a, b, c) = (a_1, \ldots, a_d, b_1, \ldots, b_d, c) \) modulo \( m \), that is

\[
F = \{(s_1, \ldots, s_d, t_1, \ldots, t_d, u) : s_i = a_i, t_i = b_i, u = c \pmod{m} \text{ for } i = 1, \ldots, d\}.
\]

The automaton \( Q \) accepts a word \( w \in \{A_1, \ldots, A_k\}^* \) if after reading \( w \) it reaches the final state from \( F \) and the values of the registers \( R_1, \ldots, R_d \) and \( T_1, \ldots, T_d \) are equal to \( a_1, \ldots, a_d \) and \( b_1, \ldots, b_d \), respectively. By construction, the language of \( Q \) in non-empty if and only if \( \langle G \rangle \) contains a matrix \( B = (a, b, c') \) with \( c' \equiv c \pmod{m} \).

Note that after reading any letter the registers of \( Q \) are changed by constant values, and the transitions have no guards or zero checks. Let \( S \) be the set of values that the registers of \( Q \) can have when it reaches the final state. It is well-known that for a register automaton of this type the set \( S \) is effectively semilinear (see [22, 21] for details). In particular, we can decide whether \( S \) contains the vector \((a, b)\), and so the emptiness problem for \( Q \) is decidable. Hence, in the case when \( G_0 \) is not commutative the Membership Problem for \( H(n, \mathbb{Z}) \) is decidable.

**Corollary 8.** The Membership Problem for \( H(n, Q) \) is decidable.

**Proof.** Let \( A_i = (a_i, b_i, c_i) \), for \( i = 1, \ldots, k \), and \( A = (a, b, c) \) be the given generators and the target matrix from \( H(n, Q) \). Let \( N \) be a natural number such that \( A_i = (\frac{1}{N}a_i^f, \frac{1}{N}b_i^l, \frac{1}{N}c_i') \), for \( i = 1, \ldots, k \), and \( A = (\frac{1}{N}a', b', c') \), where \( a_i^f, b_i^l, c_i' \), for \( i = 1, \ldots, k \), and \( a', b', c' \) are integer vectors and numbers. It is easy to check that

\[
\left(\frac{1}{N}x, \frac{1}{N}y, \frac{1}{N}c\right) \cdot \left(\frac{1}{N}x', \frac{1}{N}y', \frac{1}{N}c'\right) = \left(\frac{1}{N}(x + x'), \frac{1}{N}(y + y'), \frac{1}{N}(c + c' + x^\top y')\right).
\]

Hence \( A \in \langle A_1, \ldots, A_k \rangle \) iff \( A' \in \langle A'_1, \ldots, A'_k \rangle \), where \( A' = (a', b', c') \) and \( A'_i = (a_i^f, b_i^l, c_i') \), for \( i = 1, \ldots, k \), are matrices with integer entries, that is, from \( H(n, \mathbb{Z}) \). By Theorem 7 we can decide whether \( A' \in \langle A'_1, \ldots, A'_k \rangle \). \(\blacksquare\)
4 The Half-Space Reachability Problem for $GL(2, \mathbb{Z})$

In this section we will show that the Half-Space Reachability Problem for $GL(2, \mathbb{Z})$ is decidable (Theorem 17).

Definition 9. For an integer $n$, the sign of $n$ as follows: $\text{sg}(n) = 1$ if $n > 0$, $\text{sg}(n) = -1$ if $n < 0$, and $\text{sg}(n) = *$ if $n = 0$.

For a matrix $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathbb{Z}^{2 \times 2}$, define $\text{sg}(A) := \begin{pmatrix} \text{sg}(a) & \text{sg}(b) \\ \text{sg}(c) & \text{sg}(d) \end{pmatrix}$.

If $A$ and $B$ are two expressions whose values are in the set $\{1, -1, *\}$, then the notation $A \simeq B$ means that $A = B$ or $A = *$ or $B = *$.

Proposition 10. Suppose $w$ is a canonical word of the form $w = SR^{\alpha_1}SR^{\alpha_2} \cdots SR^{\alpha_n}$, where $\alpha_i \in \{1, 2\}$ for $i = 1, \ldots, n$. Then $\text{sg}(\varphi(w)) \simeq \begin{pmatrix} (-1)^n & (-1)^n \\ (-1)^n & (-1)^n \end{pmatrix}$.

Proof. The proof is by induction on $n$. For $n = 1$, we have

$$\text{sg}(\varphi(SR)) = \text{sg} \begin{pmatrix} -1 & -1 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} \text{sg}(-1) & \text{sg}(-1) \\ \text{sg}(0) & \text{sg}(-1) \end{pmatrix} \simeq \begin{pmatrix} -1 & -1 \\ -1 & -1 \end{pmatrix} \text{ and}$$

$$\text{sg}(\varphi(SR^2)) = \text{sg} \begin{pmatrix} -1 & 0 \\ -1 & -1 \end{pmatrix} = \begin{pmatrix} \text{sg}(-1) & \text{sg}(0) \\ \text{sg}(-1) & \text{sg}(-1) \end{pmatrix} \simeq \begin{pmatrix} -1 & -1 \\ -1 & -1 \end{pmatrix}$$

Suppose the statement of the proposition is true for $w = SR^{\alpha_1}SR^{\alpha_2} \cdots SR^{\alpha_n}$ and consider the words $wSR$ and $wSR^2$. Assume that $\varphi(w) = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ and $\text{sg}(\varphi(w)) = \begin{pmatrix} \text{sg}(a) & \text{sg}(b) \\ \text{sg}(c) & \text{sg}(d) \end{pmatrix} \simeq \begin{pmatrix} (-1)^n & (-1)^n \\ (-1)^n & (-1)^n \end{pmatrix}$. Then we have

$$\varphi(wSR) = \varphi(w)\varphi(SR) = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} -1 & -1 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} -a & -a - b \\ -c & -c - d \end{pmatrix} \text{ and}$$

$$\varphi(wSR^2) = \varphi(w)\varphi(SR^2) = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} -1 & 0 \\ -1 & -1 \end{pmatrix} = \begin{pmatrix} -a - b & -b \\ -c - d & -d \end{pmatrix}.$$

From these formulas it not hard to see that $\text{sg}(\varphi(wSR)) \simeq \begin{pmatrix} (-1)^{n+1} & (-1)^{n+1} \\ (-1)^{n+1} & (-1)^{n+1} \end{pmatrix}$ and $\text{sg}(\varphi(wSR^2)) \simeq \begin{pmatrix} (-1)^{n+1} & (-1)^{n+1} \\ (-1)^{n+1} & (-1)^{n+1} \end{pmatrix}$. \hfill □

Proposition 11. Let $w$ be a canonical word of the form $w = S^{\beta}R^{\alpha_1}SR^{\alpha_2} \cdots SR^{\alpha_n}S^\varepsilon$, where $\beta, \varepsilon \in \{0, 1\}$ and $\alpha_i \in \{1, 2\}$, $i = 1, \ldots, n$. Then $\text{sg}(\varphi(w)) \simeq \begin{pmatrix} (-1)^n & (-1)^{n+\varepsilon} \\ (-1)^{n-1+\beta} & (-1)^{n-1+\beta+\varepsilon} \end{pmatrix}$.

Proof. First, consider the case when $\varepsilon = 0$. Suppose $\varphi(SR^{\alpha_1}SR^{\alpha_2} \cdots SR^{\alpha_n}) = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$. Then by Proposition 10 we have

$$\text{sg}(\varphi(SR^{\alpha_1}SR^{\alpha_2} \cdots SR^{\alpha_n})) = \begin{pmatrix} \text{sg}(a) & \text{sg}(b) \\ \text{sg}(c) & \text{sg}(d) \end{pmatrix} \simeq \begin{pmatrix} (-1)^n & (-1)^n \\ (-1)^n & (-1)^n \end{pmatrix}.$$
On the other hand, \( \varphi(R^{a_1} S R^{a_2} \cdots S R^{a_n}) = \)
\begin{equation*}
= -\varphi(S) \varphi(R^{a_1} S R^{a_2} \cdots S R^{a_n}) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} c & d \\ -a & -b \end{pmatrix}.
\end{equation*}
Hence \( \text{sg}(\varphi(R^{a_1} S R^{a_2} \cdots S R^{a_n})) = \begin{pmatrix} \text{sg}(c) & \text{sg}(d) \\ \text{sg}(-a) & \text{sg}(-b) \end{pmatrix} \approx \begin{pmatrix} (-1)^n & (-1)^n \\ (-1)^{n-1} & (-1)^{n-1} \end{pmatrix} \).
Thus, for \( \beta \in \{0, 1\} \), we showed that
\begin{equation}
\text{sg}(\varphi(S^\beta R^{a_1} S R^{a_2} \cdots S R^{a_n})) \approx \begin{pmatrix} (-1)^n & (-1)^n \\ (-1)^{n-1+\beta} & (-1)^{n-1+\beta} \end{pmatrix}.
\end{equation}
Now assume \( \varepsilon = 1 \) and let \( \varphi(S^\beta R^{a_1} S R^{a_2} \cdots S R^{a_n}) = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \). Then
\begin{equation*}
\varphi(S^\beta R^{a_1} S R^{a_2} \cdots S R^{a_n} S) = \varphi(S^\beta R^{a_1} S R^{a_2} \cdots S R^{a_n}) \varphi(S) = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} b & -a \\ d & -c \end{pmatrix}.
\end{equation*}
From equations (7) and (8) we obtain
\begin{equation*}
\text{sg}(\varphi(S^\beta R^{a_1} S R^{a_2} \cdots S R^{a_n} S)) = \begin{pmatrix} \text{sg}(b) & \text{sg}(-a) \\ \text{sg}(d) & \text{sg}(-c) \end{pmatrix} \approx \begin{pmatrix} (-1)^n & (-1)^n \\ (-1)^{n-1+\beta} & (-1)^{n-1+\beta+1} \end{pmatrix}.
\end{equation*}
Equations (7) and (9) imply that for any \( \beta, \varepsilon \in \{0, 1\} \) \( \text{sg}(\varphi(S^\beta R^{a_1} S R^{a_2} \cdots S R^{a_n} S^\varepsilon)) \approx \begin{pmatrix} (-1)^n & (-1)^{n+\varepsilon} \\ (-1)^{n-1+\beta} & (-1)^{n-1+\beta+\varepsilon} \end{pmatrix} \).
From Proposition 11 and the equalities
\begin{align*}
\varphi(X) \begin{pmatrix} a & b \\ c & d \end{pmatrix} &= \begin{pmatrix} -a & -b \\ -c & -d \end{pmatrix} \quad \text{and} \quad \varphi(N) \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a & b \\ -c & -d \end{pmatrix}
\end{align*}
we obtain the following proposition.

**Proposition 12.** Let \( w \) be a canonical word of the form \( w = N^{\delta} X^\gamma S^\delta R^{a_1} S R^{a_2} \cdots S R^{a_n} S^\varepsilon \), where \( \beta, \gamma, \delta, \varepsilon \in \{0, 1\} \) and \( \alpha_i \in \{1, 2\} \) for \( i = 1, \ldots, n \). Then
\begin{equation*}
\text{sg}(\varphi(w)) \approx \begin{pmatrix} (-1)^{n+\gamma} & (-1)^{n+\gamma+\varepsilon} \\ (-1)^{n-1+\beta+\gamma+\delta} & (-1)^{n-1+\beta+\gamma+\delta+\varepsilon} \end{pmatrix}.
\end{equation*}

**Theorem 13.** The set of matrices in \( \text{GL}(2, \mathbb{Z}) \) whose particular entry is nonnegative forms a regular subset. In other words, for all \( i, j \in \{1, 2\} \), the following subset of \( \text{GL}(2, \mathbb{Z}) \) is regular:
\begin{equation*}
\text{Pos}_{ij} = \left\{ \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \in \text{GL}(2, \mathbb{Z}) : a_{ij} \geq 0 \right\}.
\end{equation*}

**Proof.** Suppose \( i = j = 2 \) as other cases are similar. Let \( A \) be a matrix from \( \text{GL}(2, \mathbb{Z}) \) and let \( w = N^{\delta} X^\gamma S^\delta R^{a_1} S R^{a_2} \cdots S R^{a_n} S^\varepsilon \), where \( \beta, \gamma, \delta, \varepsilon \in \{0, 1\} \) and \( \alpha_i \in \{1, 2\} \) for \( i = 1, \ldots, n \), be a canonical word that represents \( A \), that is, \( A = \varphi(w) \). From Proposition 12 we see that \( \text{sg}(a_{22}) \approx (-1)^{n-1+\beta+\gamma+\delta+\varepsilon} \). Hence
\begin{equation}
a_{22} \geq 0 \quad \text{if and only if} \quad n - 1 + \beta + \gamma + \delta + \varepsilon \equiv 0 \quad (\text{mod } 2).
\end{equation}
To finish the proof, we note that the set of all canonical words is regular. Furthermore, given a canonical word of the form \( w = N^\beta X^\gamma S^\delta R^{\epsilon_1} S R^{\epsilon_2} \cdots S R^{\epsilon_n} S^2 \), a finite automaton can read off the values of \( \beta, \gamma, \delta, \epsilon \) and determine the parity of number \( n \). From this data an automaton can decide whether \( \epsilon_2 \geq 0 \) by the above mentioned equivalence (10). Hence the set of canonical words \( w \) such that \( \varphi(w) \in Pos_{22} \) can be recognised by a finite automaton. ▶

Next theorem was proved in [33].

**Theorem 14.** For every \( k \in \mathbb{Z} \), the following subset of \( GL(2, \mathbb{Z}) \) is regular:

\[
S_{ij}(k) = \left\{ \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \in GL(2, \mathbb{Z}) : a_{ij} = k \right\}.
\]

As a corollary from Theorems 13 and 14 we obtain:

**Theorem 15.** For every \( k \in \mathbb{Z} \), the following subsets of \( GL(2, \mathbb{Z}) \) are regular:

\[
S_{ij}(\geq k) = \left\{ \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \in GL(2, \mathbb{Z}) : a_{ij} \geq k \right\}
\]

\[
S_{ij}(\leq k) = \left\{ \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \in GL(2, \mathbb{Z}) : a_{ij} \leq k \right\}.
\]

**Proof.** Since \( S_{ij}(\leq k) \) is the complement of \( S_{ij}(\geq k+1) \), it suffices to prove that the sets \( S_{ij}(\geq k) \) are regular.

If \( k = 0 \), then it follows from Theorem 13 that \( S_{ij}(\geq 0) = Pos_{ij} \) is regular. Furthermore,

\[
S_{ij}(\geq k) = Pos_{ij} \setminus \bigcup_{n=0}^{k-1} M_{ij}(n) \quad \text{if } k > 0 \quad \text{and} \quad S_{ij}(\geq k) = Pos_{ij} \cup \bigcup_{n=k}^{-1} M_{ij}(n) \quad \text{if } k < 0.
\]

Since by Corollary 6 regular subsets of \( GL(2, \mathbb{Z}) \) are closed under Boolean operations, we conclude that \( S_{ij}(\geq k) \) is a regular set for any \( k \in \mathbb{Z} \). ▶

**Theorem 16.** Let \( \lambda \in \mathbb{Q} \) and \( u, v \in \mathbb{Q} \times \mathbb{Q} \). Then the set \( S(u, v, \lambda) = \{ M \in GL(2, \mathbb{Z}) : u^T M v \geq \lambda \} \) is a regular subset of \( GL(2, \mathbb{Z}) \).

**Proof.** Note that if \( u = 0 \) or \( v = 0 \), then \( u^T M v = 0 \). In this case \( S(u, v, \lambda) \) equals either the empty set or \( GL(2, \mathbb{Z}) \), both of which are regular subsets. Hence we will assume that both \( u \) and \( v \) are nonzero vectors. By multiplying the inequality \( u^T M v \geq \lambda \) by the least common multiple of the denominators of \( u_1, u_2, v_1, v_2 \), we can assume that \( u \) and \( v \) have integer coefficients. Furthermore, we can divide \( u^T M v \geq \lambda \) by \( \gcd(u_1, u_2) \) and \( \gcd(v_1, v_2) \) and so assume from now on that \( \gcd(u_1, u_2) = \gcd(v_1, v_2) = 1 \).

Finally, note that the inequality \( u^T M v \geq \lambda \) is equivalent to \( u^T M v \geq [\lambda] \), where \([\lambda] = \min\{n \in \mathbb{Z} : n \geq \lambda\} \). So, we can assume that \( \lambda \) is also an integer number.

Since \( \gcd(u_1, u_2) = \gcd(v_1, v_2) = 1 \), there are integers \( s_1, s_2, t_1, t_2 \) such that \( s_1 u_1 + s_2 u_2 = 1 \) and \( t_1 v_1 + t_2 v_2 = 1 \). Hence the matrices \( A = \begin{pmatrix} u_1 & -s_2 \\ u_2 & s_1 \end{pmatrix} \) and \( B = \begin{pmatrix} v_1 & -t_2 \\ v_2 & t_1 \end{pmatrix} \) belong to \( GL(2, \mathbb{Z}) \), and we have that \( u = Ae_1 \) and \( v = Be_1 \). Therefore, the inequality \( u^T M v \geq \lambda \) is equivalent to \( e_1^T A^T M B e_1 \geq \lambda \). In other words,

\[
M \in S(u, v, \lambda) \iff A^T M B \in S_{11}(\geq \lambda) \iff M \in (A^T)^{-1} \cdot S_{11}(\geq \lambda) \cdot B^{-1}.
\]
By Theorem 15, $S_{11}(\geq \lambda)$ is a regular subset of $GL(2, \mathbb{Z})$. Let $L$ be a regular language and let $w_1, w_2$ be canonical words such that $\varphi(L) = S_{11}(\geq \lambda)$ and $\varphi(w_1) = (A^T)^{-1}$ and $\varphi(w_2) = B^{-1}$. Then $\{w_1\} \cdot L \cdot \{w_2\}$ is a regular language such that $\varphi(\{w_1\} \cdot L \cdot \{w_2\}) = (A^T)^{-1} \cdot S_{11}(\geq \lambda) \cdot B^{-1} = S(u, v, \lambda)$.

**Theorem 17.** The Half-Space Reachability Problem for $GL(2, \mathbb{Z})$ is decidable.

**Proof.** Let $G = \{A_1, \ldots, A_k\}$ be a finite collection of matrices from $GL(2, \mathbb{Z})$, $\lambda$ be a rational number and $u, v$ be vectors from $\mathbb{Q}^2$. Define $S(u, v, \lambda) := \{M \in GL(2, \mathbb{Z}) : u^T M v \geq \lambda\}$.

By Theorem 16, $S(u, v, \lambda)$ is a regular subset of $GL(2, \mathbb{Z})$. Let $L_S$ be a regular language such that $S(u, v, \lambda) = \varphi(L_S)$. It is not hard to see that the semigroup $\langle G \rangle$ is also a regular subset.

Indeed, consider a regular language $L'_G = (w_1 \cup \cdots \cup w_k)^+$, where $w_1, \ldots, w_k$ are canonical words that correspond to the matrices $A_1, \ldots, A_k$, respectively. Then $\langle G \rangle = \varphi(L'_G)$.

By Corollary 6, we can algorithmically construct a regular language $L'' \cap \varphi(L'_G)$.

Given a sequence $\{w_1, \ldots, w_k\}$ of matrices, we can express the product of the sequence $L''$ as follows:

$$L'' = \{w_1 \cdot \cdots \cdot w_k\} \subseteq L''$$

The last condition is equivalent to $L'' \neq \emptyset$. Therefore, we reduced the Half-Space Reachability Problem for $GL(2, \mathbb{Z})$ to the emptiness problem for regular languages.

5 The Half-Space Reachability Problem for the Heisenberg Group

**Definition 18.** Let $S := B_1, \ldots, B_m$ be a sequence in $H(n, \mathbb{Q})$ and $A$ a particular matrix in $H(n, \mathbb{Q})$. A pair $i, j$ in $\{1, \ldots, m\}$ with $i \leq j$ is called an A-block of $S$ if

1. $B_k = A$ for all $k \in \{i, \ldots, j\}$,
2. either $i = 1$ or $B_{i-1} \neq A$,
3. either $j = m$ or $B_{j+1} \neq A$.

We say that $S$ is pure if it has at most one A-block for every matrix $A$.

Given a sequence $S = B_1, \ldots, B_m \in H(n, \mathbb{Q})$, define $C_i := \log(B_i)$ for $i = 1, \ldots, m$, $\Delta(S) := \sum_{1 \leq i < j \leq m} [C_i, C_j]$, and $\delta(S) := \Delta(S)_{1,n}$. Recall that using the Baker-Campbell-Hausdorff formula (3) we can express the product of the sequence $S$ as follows

$$B_1 \cdots B_m = \exp \left( \sum_{i=1}^{m} C_i + \frac{1}{2} \sum_{1 \leq i < j \leq m} [C_i, C_j] \right)$$

**Proposition 19.** For any sequence of matrices $S = B_1, \ldots, B_m \in H(n, \mathbb{Q})$, there is a permutation $\pi \in S_m$ such that sequence $S' := B_{\pi(1)}, \ldots, B_{\pi(m)}$ is pure and $\delta(S) \leq \delta(S')$.

The proof of Proposition 19 can be found in the full version [11].

**Theorem 20.** The Half-Space Reachability Problem for $H(n, \mathbb{Q})$ is decidable.

**Proof.** Consider an instance of the Half-Space Reachability Problem, given by a finite set $G = \{A_1, \ldots, A_k\} \subseteq H(n, \mathbb{Q})$ of generators, vectors $u, v \in \mathbb{Q}^n$, and a scalar $\lambda \in \mathbb{Q}$.

Given a sequence $S = B_1, \ldots, B_m$ of elements of $G$ and a permutation $\sigma \in \text{Sym}_m$, define $S_{\sigma} := B_{\sigma(1)} \cdots B_{\sigma(m)}$. It follows from Equation (11) that the entries of the product $B_{\sigma(1)} \cdots B_{\sigma(m)}$ do not depend on the choice of $\sigma \in \text{Sym}_m$, except for the $(1,n)$-entry which is equal to $\frac{1}{2} \Delta(S_{\sigma})_{1,n}$ plus a constant that also does not depend on $\sigma$. So, the permutation
\( \sigma \) that maximises \( u^\top B_{\sigma(1)} \cdots B_{\sigma(n)}v \) is the same which maximises or minimises \( \Delta(S_\sigma)_{1,n} \) depending on the sign of the coefficient at \( \Delta(S_\sigma)_{1,n} \) in the expression \( u^\top \Delta(S_\sigma)v \), namely, on the sign of \( u_1v_n \). By Proposition 19 we may assume without loss of generality that the optimal permutation \( \sigma \) is such that \( S_\sigma \) is pure.

By the reasoning above, to decide the given instance of the Half-Space Reachability Problem it suffices to restrict attention to pure sequences of generators. Equivalently we must decide whether there exist nonnegative integers \( n_1, \ldots, n_k \) and a permutation \( \sigma \in \text{Sym}_k \) such that

\[
\begin{align*}
    u^\top A_{\sigma(1)}^{n_1} \cdots A_{\sigma(k)}^{n_k} v &= u^\top \exp \left( \sum_{i=1}^k n_i C_{\sigma(i)} + \frac{1}{2} \sum_{i<j} n_i n_j [C_{\sigma(i)}, C_{\sigma(j)}] \right) v \\
    &= Q(n_1, \ldots, n_k)
\end{align*}
\]

for some quadratic polynomial \( Q(x_1, \ldots, x_k) \) with rational coefficients.

In the work of Grunewald and Segal [14] an algorithm is given for solving the following problem: does there exist integers \( n_1, \ldots, n_k \) that satisfy a given quadratic equation \( Q(n_1, \ldots, n_k) = 0 \) (with rational coefficients) and a finite number of linear inequalities on \( n_1, \ldots, n_k \) (also with rational coefficients).

By introducing a “dummy” variable we can use the Grunewald and Segal algorithm to decide whether \( Q(n_1, \ldots, n_k) \geq \lambda \) for some nonnegative integers \( n_1, \ldots, n_k \). Hence the Half-Space Reachability Problem for \( H(n, Q) \) is decidable.
